Sent for review: 7 July 2021

Revised accepted: 11 October 2021

Abstract

Purpose: To investigate the effectiveness and safety of the combination of Kanglaite injection (KLTi) and gemcitabine and cisplatin (GP) chemotherapy in the treatment of advanced non-small cell lung cancer (NSCLC).

Methods: PubMed, Web of Science, Embase, Cochrane Library, CNKI, Wan-Fang, CBM, and CQVIP were comprehensively searched from January 2010 till November 2020. Randomized controlled trials (RCTs) of KLTi plus GP in the treatment of NSCLC were selected and assessed for inclusion. Review Manager 5.3 software was used for meta-analysis.

Results: Twenty-five RCTs on advanced NSCLC examined the inclusion criteria. The meta-analysis showed that compared with GP chemotherapy alone, KLTi plus GP chemotherapy significantly improved objective response rate (ORR) (RR = 1.36, 95% CI 1.23-1.51, p < 0.00001), disease control rate (DCR) (RR = 1.17, 95% CI 1.11 - 1.23, p < 0.00001), and reduced adverse drug reactions(ADRs) such as hair loss (RR = 0.60, 95% CI 0.47 - 0.76, p < 0.0001), gastrointestinal reaction (RR = 0.68, 95% CI 0.62 - 0.75, p < 0.00001), impairment of liver and kidney function (RR = 0.65, 95% CI 0.53 - 0.80, p < 0.001), nervous system damage (RR = 0.42, 95% CI 0.26 - 0.69, p = 0.0005), myelosuppression (I-II phase) (RR = 0.79, 95 % CI 0.66 - 0.95, p = 0.01), myelosuppression (III-IV phase) (RR = 0.44, 95 % CI 0.27 - 0.72, p = 0.001), anemia (RR = 0.74, 95 % CI 0.60 - 0.91, p = 0.006), leukopenia (RR = 0.78, 95% CI 0.69, 0.87, p < 0.0001), thrombocytopenia (RR = 0.59, 95 % CI 0.49, 0.72, p < 0.0001), hypochromia (RR = 0.74, 95% CI 0.59, 0.92, p = 0.008).

Conclusion: KLTi adjuvant GP chemotherapy reduces adverse effects in patients with advanced NSCLC. Thus, KLTi might be an effective and safe intervention for NSCLC.

INTRODUCTION

At present, lung cancer is still one of the major diseases that threaten human health. In recent decades, the morbidity and mortality rates of lung cancer have witnessed a significant increase. In 2018, the International Agency for Research on Cancer reported that global new cases of cancer reached 18.1 million, out of which 9.6 million are reported to have died. Irrespective of gender, lung cancer is the most commonly diagnosed cancer (11.6% of total cases) and the leading cause of cancer death (18.4% of the total cancer deaths) [1]. However, in 2020, 19.3 million cases were diagnosed new cases of cancer, with almost 10.0 million deaths according to the International Agency for Research on Cancer. Female breast cancer has surpassed lung cancer for the first time as the most commonly diagnosed cancer. Lung cancer however, is still the leading cause of cancer-related death, with an estimated 1.8 million deaths (18%). In China, there were 4.57 million new cancer cases in 2020, with lung cancer cases at 0.82 million. In addition, the incidence of lung cancer still ranks first: the number of cancer deaths is 3 million, of which lung cancer is as high as 0.71 million [2].

Chemotherapy is one of the main treatment methods for advanced NSCLC. The GP regimen is considered to be the main regimen used to treat advanced NSCLC, in which cisplatin destroys DNA function, blocks its replication, and plays an anti-cancer effect by linking with DNA strands. Gemcitabine has also a certain effect on DNA, which could repair inhibition and enhance the anti-cancer effect by combining with cisplatin [3]. However, there are many adverse reactions to GP chemotherapy. Where patients have a poor record of physical fitness and poor chemotherapy tolerance, chemotherapy poses the risk of exacerbating their suffering, thus affecting the quality of their lives. It is therefore necessary to find an effective drug that can mitigate the effects of chemotherapy on patients with advanced non-small-cell lung cancer, and improve their quality of life.

Kanglaite injection (KLTi) is extracted from the traditional Chinese medicine Coix seed, which has the dual effects of anti-tumor and immune function regulation. Studies have shown that KLTi not only enhances the effects of chemotherapy for NSCLC and reduces adverse reactions, it also improves the immune function of patients [4,5]. Therefore, this study aims to conduct a comprehensive meta-analysis of the results of clinical randomized controlled trials (RCTs) on KLTi plus chemotherapy, as well as systematically evaluate the efficacy and safety of

KLTi adjuvant chemotherapy for advanced NSCLC.

METHODS

This meta-analysis was strictly performed following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines [6]. Ethical approval was not necessary since meta-analysis was based on secondary data, and did not involve any individual patient.

Eligibility criteria

These studies were evaluated according to the following inclusion criteria: (1) locally advanced or metastatic (stages III - IV) NSCLC confirmed histologically or cytologically without surgical operations and radiotherapy to the thoracic primary lesion, as well as other traditional Chinese medicine treatment; (2) studies on randomized controlled trials (RCTs); (3) Patients in the experimental group received KLTi and GP combination chemotherapy, and patients in the control received corresponding group conventional GP chemotherapy; (4) The primary outcomes, i.e., primary tumor response rate (CR, PR, SD, PD, etc.) and toxicity, were reported. It excluded retrospective clinical trials, case reports, meeting abstracts, cohort studies, in vitro and animal studies, duplicated studies, reviews, letters, commentaries, and errata, and studies on patients that received surgery, radiotherapy, or other traditional Chinese medicine treatment during the intervention period were excluded.

Literature sources and search strategies

PubMed, Web of Science, Embase, Cochrane Library, CNKI, Wan-Fang, CBM, and CQVIP, were comprehensively searched from January 2010 to November. The following search terms were used: ("Kanglaite" [Mesh terms]) AND ("lung cancer" [Mesh terms] OR "lung Neoplasms" [Mesh terms]). Languages were limited to English and Chinese. The search results were downloaded for further evaluation.

Study selection

All studies that were utilized for this study were imported into EndNote reference management software. Two reviewers (Dong and Guo) independently assessed the titles and abstracts in strict accordance with the inclusion and exclusion criteria. A third senior investigator (Wei) resolved any disagreements between the 2 reviewers.

Definition of outcome measures

Clinical efficacy was evaluated in accordance with the Response Evaluation Criteria in Solid Tumors (RECIST), developed by World Health Organization (WHO) curative effect evaluation criteria. Enrolled patients were divided into 4 categories: complete response (CR), partial response (PR), stable disease (SD), and progressive disease (PD). Objective response rate (ORR) was considered as the primary endpoint, and ORR = [(CR + PR)/total] × 100%. Moreover, the disease control rate was defined as the objective response, that is DCR, and DCR = [(CR+PR+SD)/total] × 100%. Adverse events or adverse drug reactions (ADEs or ADRs) were classified into 0~IV levels, according to the National Cancer Institute Common Toxicity Criteria version 4.0 (CTC4.0). Adverse events include toxic reactions and adverse reactions that occur before and after treatment.

Data extraction

In each included study, the following basic information was independently obtained by two assessors: the first author's name, published year, study design and methodology, sample size, age, gender, TNM stage, and histologically type, including squamous carcinoma (SQC), adenocarcinomas, adenosquamous carcinoma (ADC), and large-cell carcinomas, and the main outcome indicators, including ORR, DCR, and ADRs.

Assessment of risk of bias (quality)

Risk of bias assessment for all studies was performed by the two assessors, according to the Cochrane risk of bias assessment. Quality assessment of each trial was evaluated by the Review Manager 5.3 according to the Cochrane Handbook for Systematic Reviews of Interventions.[6]

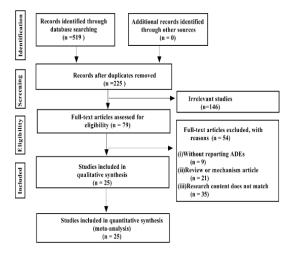

Statistical analysis

Statistical analysis was performed using Review Manager 5.3 software. Risk ratios (RRs) with 95 % confidence interval (95 % Cl) were calculated for dichotomous variables. Heterogeneity was evaluated according to the magnitude of p-value and l^2 index. Significant heterogeneity was present when $l^2 > 50$ %, while non-significant heterogeneity was considered when p > 0.05 and $l^2 \le 50$ %. Thus, a fixed-effect model was adopted when heterogeneity was used to explore heterogeneity where necessary. Funnel plots were used to assess publication bias.

RESULTS

Selected literature

Following the PRISMA, Figure 1 flow diagram illustrated the selection process of eligible studies. Databases were retrieved and 519 records were identified based on the established search strategy. The 294 duplicate records were excluded after their titles and abstracts were screened. Furthermore, full-text articles of 79 publications were assessed for eligibility, of which 54 were excluded because they did not report ADEs, reviews, or mechanistic articles, and the study content was inconsistent. Finally, 25 reports were included in the meta-analysis, and 2194 patients (experimental groups: 1100 cases; control groups: 1094 cases) who met the inclusion criteria were included, and data was extracted from these trials and used for the qualitative analysis.

Characteristics of included studies

Table 1, Table 2, Table 3, Table 4 and Table 5 showed the characteristics of the included studies. All the selected literature had been published in China between 2010 and 2020 with no significant baseline differences. All the studies were RCTs. The age range was 27 - 78 years, with males and females totaling 1386 and 878 in number respectively (Table 1). The main types of the pathology of advanced NSCLC consisted of squamous cell carcinoma, adenocarcinomas, adenosquamous carcinoma, and large cell carcinomas (Table 2). Twenty-five studies were phase III-IV phase studies, and they all reported outcomes of clinical efficacy and adverse reactions. Twenty-two studies reported KLTi was administered intravenously at 200 mL/time, 1 to 3

week/cycle, and 1 to 4 cycles (Table 3). All adverse reactions were reported in the trials, including myelosuppression, hair loss, gastrointestinal reaction, impairment of liver and kidney function and nervous system damage, of which anemia, leukopenia, thrombocytopenia, decreased hemoglobin, were observed in myelosuppression (Table 4 and Table 5).

Risk of bias in included trials

According to the Cochrane risk of bias estimation, the risk of bias was evaluated for each study included in the trial. All included studies mentioned "random", of which only ten studies [9,11,14,18,23,24,26-29] definitely referred to random number table, and one trial [8] with random drawing. No trial reported information on allocation concealment, blinding of participants and personnel, or blinding of outcome assessment (Figure 2).

Clinical efficacy analysis

All 25 trials [3,5,7-29] reported the efficacy of tumor responses in detail (Figures 3 and 4). The

ORR and DCR were used to assess the shortterm efficacy, according to the RECIST criteria. There was no statistical heterogeneity among the trials in the ORR (p = 0.94, $l^2 = 0\%$) and DCR (p = 0.71, $l^2 = 0\%$), respectively. Therefore, the fixed effect model was applied in this pooled analysis. Our results indicated that KLTi combined with GP chemotherapy was superior to GP chemotherapy in terms of ORR (RR = 1.36, 95% CI 1.23 - 1.51, p < 0.00001)) and DCR (RR = 1.16, 95% CI 1.11 - 1.23, p < 0.00001).

Subgroup analysis

The subgroup analysis was performed in order to examine the effect of different doses or cycles KLTi united GP regimens on ORR and DCR. The doses of KLTi were 100 mL/day in two trials [14,23], and in another trial it was 60 ml/day [7]. In the other 22 studies [5,8-13,15-22,24-29], the dose of KLTi was 200 mL/day. In the subgroup analysis, it was found that irrespective of the dosage of KLTi that was combined with GP, the ORR and DCR (Figures 5 and 6) could be improved.

Figure 6: Subgroup analysis of disease control rate (DCR)

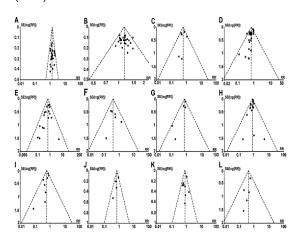

Figure 7: Publication bias analysis. Funnel plot of ORR (A), DCR (B), Hair loss (C), Gastrointestinal reaction (D), Impairment of liver and Kidney's function (E), Nervous system damage (F), Anemia (G), Leukopenia (H), Thrombocytopenia (I), Hemoglobin decreased (J), I-II phase myelosuppression (K), III-IV phase myelosuppression (L)

ADRs

A meta-analysis of the 25 included RCTs [3,5,7-29] showed ADRs of KLTi in combination with GP chemotherapy for treating advanced NSCLC, including myelosuppression, hair loss, gastrointestinal reaction, impairment of liver and kidney function, and nervous system damage. Moreover, myelosuppression, anemia, leukopenia, thrombocytopenia, decreased haemoglobin were observed. It was found that the incidence of ADRs in the experiment group had a significantly lower level than the control group, except that there was no remarkably different incidence of I-II phase myelosuppression.

Publication bias

The publication bias was evaluated using the symmetrical funnel plots for ORR, DCR, the hair loss, gastrointestinal reaction, impairment of liver and kidney function, nervous system damage, anemia, leukopenia, thrombocytopenia, decreased hemoglobin, I-II phase myelosuppression, III-IV phase myelosuppression (Figure 7).

DISCUSSION

The findings of this meta-analysis indicate that combined KLTi and GP regimens can be an effective and safe method for the treatment of advanced NSCLC. This combination therapy model achieved favorable lung primary lesion response rates and superior survival rates with mild-to-moderate side effects. However, it should be noted that the quality of evidence supporting these findings is low.

Chemotherapy has generally been the firstchoice treatment option for advanced NSCLC. Gemcitabine and Cisplatin regimen is one of the effective treatment choices. Gemcitabine (2'. 2'difluorodeoxycytidine) is a chemotherapeutic agent that inhibits DNA synthesis in dividing cells [30], and it is a third-generation cell cycle-specific three anti-tumor drua with anti-tumor mechanisms. In addition, Gemcitabine has relatively mild side effects, high safety, and low local irritation. Also, it is well tolerated by patients. At present, it is widely used in non-small cell lung cancer [3,5,7-29], pancreatic cancer [31], breast cancer [32], ovarian cancer [33], and bladder cancer [34], with good efficacy and safety.

Traditional Chinese medicine (TCM) injections are composed of active ingredients extracted from TCM or natural medicines using modern techniques and methods according to the theory and experience of TCM. KLTi is a novel antitumor Chinese medicine (TCMs) developed in China. It is a representative product of domestic Chinese medicine anti-tumor injections. Its main component is coix seed triglyceride, which has anti-tumor and immunity enhancement effects [35].

Kanglaite is an NF-kB inhibitor. In the study of four colorectal cancer cell lines HCT106,

HCT116, LoVo, and CT26, it was found that tumor necrosis factor-alpha-mediating the activation of NF-kB, caused changes in epithelial-mesenchymal transition-related protein expression and increased migration and invasion in all four cell lines. However, these effects were inhibited by Kanglaite when used in combination tumor necrosis factor-alpha. with In а subcutaneous tumor model of CT26, tumor necrosis factor-alpha enhanced the tumorigenic ability of the cells, and again this was inhibited by Kanglaite. However, treatment with Kanglaite alone caused almost no inhibition of epithelialmesenchymal transition-mediated tumor growth, when cells were pretreated with tumor necrosis factor-alpha prior to injection. These results suggest that Kanglaite inhibits tumor necrosis factor-alpha-mediated epithelial-mesenchymal transition in colorectal cancer cell lines via the inhibition of NF-κB [36].

Another research demonstrated that Kanglaite markedly decreased the regulation of NF-kB/lkB expression and significantly increased the level of IL-2 and EGFR in C57BL/6 mice with Lewis lung carcinoma. Thus, KLTi has pronounced antitumor and immunostimulatory activities in C57BL/6 mice with Lewis lung carcinoma [37]. Clinically, kanglaite significantly reduces the expression of miRNA-21 in patients with advanced lung cancer, and provides objective evidence for the treatment of lung cancer [38]. In this comprehensive systematic review and metaanalysis, we comprehensively evaluated whether KLTi combined with GP chemotherapy versus GP chemotherapy alone would benefit patients with advanced NSCLC. Our results suggest that KLTi not only statistically improves clinical efficacy, it also reduces adverse reactions in advanced NSCLC.

In our meta-analysis, the clinical results were divided into objective response rate (ORR) and disease control rate (DCR). The results indicate that KLTi possesses superior clinical efficacy when combined with GP chemotherapy for the treatment of advanced NSCLC, and these results are consistent with previous studies [3,14]. Moreover, we found that KLTi combined with GP chemotherapy, reduced the incidence of adverse reactions in patients with advanced NSCLC. Appropriate drug selection is a major challenge in patients with advanced NSCLC, especially those who have complications from concomitant gastrointestinal system and circulatory diseases [35]. This study has certain limitations. First, the RCTs were uncommon in the use of KLTi in the treatment of advanced NSCLC. The descriptions of random sequence generation, allocation concealment, and blinding methods of the

included clinical trials were not detailed, which might result in selected bias. As a result, there mav been some overestimation or underestimation of the impact of KLTi. Furthermore, the different stages of TNM and the pathological type diversity of the trials included in the study could form unbalanced baselines. Third, the use of different doses of KLTi in chemotherapy combination with and administration patterns may affect the efficacy and safety evaluation. Fourth, all included studies were published in Chinese, so the results of this systematic review may be affected by potential publication bias. In conclusion, for the clinical efficacy and safety of TCM, well-designed RCTs with large sample size and double-blind are needed for further assessment, so that Chinese TCM can be approved in international markets.

CONCLUSION

On the basis of the present meta-analysis, there is reasonable evidence that the combination of KLTi with chemotherapy may improve the ORR and survival outcomes in advanced NSCLC patients, as well as reduce the risk of hepatotoxicity, gastrointestinal reactions, neurotoxicity, and hepatotoxicity in patients with advanced NSCLC. However, a larger number of patients and prospective studies are required to fully establish the clinical efficacy and safety of this treatment.
