Abstract

**Purpose:** The aim of the present study was to investigate antioxidant and antimicrobial effects of the methanol extract of *Heracleum nepalense* D.Don roots.

**Method:** The antimicrobial effect was determined by agar dilution and disc diffusion method. The free radical scavenging potential was studied by using different antioxidants models of screening using vitamin E (5mM) as standard.

**Results:** The crude methanol extract of *H.nepalense* root was found to be active against both Gram-positive and Gram-negative organisms. The ethyl acetate soluble fraction of the extract showed similar activity against these organisms. Similarly, the methanol extract at 1000 µg. ml⁻¹ and the ethyl acetate fraction at 50 µg. ml⁻¹ exhibited significant antioxidant activity in ferrous sulphate induced lipid peroxidation, 1,1-diphenyl- 2-picryl hydrazyl (DPPH), Hydroxyl radical and Superoxide scavenging models.

**Conclusions:** The study confirms the possible antioxidant and antimicrobial potentiality of the plant extract. Presence of flavonoid alone or in combination with its other components could be responsible for the activity.

**Keywords:** Heracleum nepalense, Lipid peroxidation, Superoxide scavenging, DPPH assay, Antimicrobial effect, Flavonoid.

Introduction

Reactive oxygen species (ROS) such as superoxides, peroxides and hydroxyl radicals are known to play an important role and have been identified as major contributors to all cell and tissue damage in many disease conditions. In living organisms, various ROS can form in different ways. Normal aerobic respiration stimulates polymorphonuclear leukocytes and peroxisomes appear to be the main endogenous sources of most of the oxidants produced by cells. Exogenous sources of ROS include tobacco smoke, alcohol, pesticides, certain pollutants and microbial infections.

In recent years, there has been increased incidence of antibiotic resistance in pathogenic organisms and the persistence of pathogens in immune compromised individuals is of great concern. Therefore, actions must be taken to reduce this problem such as controlling the use of antibiotics, carrying out research to better understand the genetic mechanisms of resistance and continuing investigations aimed at the development of drugs from natural sources.

The recent years have witnessed resurgence of interest in herbal drugs globally as more people are turning to the use of herbal medicinal products in health care. About 80% of individuals from developing countries use traditional medicine, which involves compounds derived from medicinal plants. It is high time the hidden wonders of plant molecules were revived with the modern tools of target-based screening to develop newer advanced generation antioxidants and antimicrobials with novel modes of action. Antioxidants play an important role in inhibiting and scavenging free radicals, thus providing protection to human body against infection and degenerative diseases.

*Heracleum nepalense* D.Don (Apiaceae) is a small shrub occurring in Nepal and Sikkim. The plant is used in veterinary medicine. It exhibits stimulant property and increases blood pressure in goats. The roots of the plant are used in folk medicine as digestive, carminative and anti diarrhoeal (Authors personal experience). The roots of the plant are reported to have coumarins and steroids. The present study was aimed at evaluating antioxidant and antimicrobial properties of *Heracleum nepalense*.

Experimental

**Plant materials and phytochemical screening**

The fresh dried roots of *Heracleum nepalense* (HNSE) were collected from the southern district of Sikkim. The plant was authenticated by Botanical Survey of India, Gangtok, Sikkim. The voucher specimen was preserved in our laboratory for future reference. The dried roots were powdered and stored in a well-closed container. 1 kg of powder (40 mesh size) was extracted by cold percolation with 3 liters of 70% v/v methanol in a percolator for 72 h at room temperature. The residue was removed by filtration. The extract was then evaporated to dryness under reduced pressure in a rotary evaporator at 42-45°C. The concentrated extract of leaves was kept in a desiccator for further use.

The preliminary phytochemical tests of the root extract were done by Pollock and Stevens method. Concentrated methanol extract was suspended in hot distilled water, cooled and the blast precipitate was filtered off. The filtrate (aqueous solution) was fractioned by extracting it successively with petroleum ether, ethyl acetate and acetone. The ethyl acetate fraction of the crude extract on purification yielded one major fraction A (flavonoid) with some fatty substances.

**Chemicals**

Thiobarbituric acid was obtained from Loba Chemie, India. 1,1-Diphenyl-2-picryl hydrazyl (DPPH), NADH and nitroblue tetrazolium (NBT) were obtained from Sigma chemicals, St. Louis, USA. Deoxy ribose was obtained from Merck India. Dimethyl sulphotide, ethylene diamine tetra acetic acid, ferrous sulphate, trichloroacetic acid, hydrogen peroxide, ascorbic acid, mannitol, potassium dihydrogen phosphate, potassium...
hydroxide, deoxy ribose, phenazine methosulphate were of analytical grade and were obtained from Ranbaxy fine chemicals.

**Determination of antioxidant activity**

**Assay of lipid peroxidation**
The extent of lipid peroxidation in goat liver homogenate was measured *in vitro* in terms of formation of thiobarbituric acid reactive substances (TBARS) by using standard method with minor modifications. Goat liver was purchased from local slaughter house. Its lobes were dried between blotting papers (to remove excess blood) and were cut into small pieces with a heavy-duty blade. They were then homogenized in glass-Teflon homogenizing tube with a heavy-duty blade. They were then centrifuged at 2000 rpm for 10 min and supernatant was diluted with phosphate buffer saline up to final concentration of protein 0.8-1.5 mg/0.1 ml. Protein concentration was measured by using standard method of Lowery et.al. To a methanolic solution of DPPH (100 µM, 2.95ml), 0.05 ml of methanol extract as well as fraction A (25, 50 µg.ml⁻¹) and Standard compound (vitamin E) were added at different concentrations. Equal amount (0.05 ml) of methanol was added to a control. Absorbance was recorded at 517nm at regular intervals of 1 to 5 min. The percentage of scavenging was calculated by comparing the control and test samples with the Eqn 1.

**DPPH radical scavenging activity**

DPPH scavenging activity was measured by spectrophotometric method. To a methanolic solution of DPPH (100 µM, 2.95ml), 0.05 ml of methanol extract as well as fraction A (25, 50 µg.ml⁻¹) and Standard compound (vitamin E) were added at different concentrations. Equal amount (0.05 ml) of methanol was added to a control. Absorbance was recorded at 517nm at regular intervals of 1 to 5 min. The percentage of scavenging was calculated by comparing the control and test samples with the above mentioned Eqn 1.

**Hydroxyl radical scavenging activity**

Hydroxyl radical scavenging activity was measured by studying the competition between deoxy ribose and test compounds for hydroxyl radical generated by the Fe⁻³– ascorbate – EDTA – H₂O₂ system (Fenton reaction) according to the method of Kunchandy & Rao. The reaction mixture containing, a final volume of 1.0 ml, 100 µl 2-deoxy-ribose, 500 µl of the various concentrations of the methanol extract as well as fraction A (25, 50 µg.ml⁻¹) and standard compound (Mannitol 50 mM) in KH₂PO₄- KOH buffer (20mM, pH 7.4), 200 µl 1.04 mM H₂O₂ and 100 µl 1.0mM ascorbic acid was incubated at 37°C for 1 hour. One millilitre 1% trichloroacetic acid was added to each test tube and incubated at 100°C for 20 min. After cooling to room temperature, absorbance was measured at 532nm against a control preparation containing deoxyribose and buffer. Percent inhibition was determined by comparing the results of the test and control samples with the above mentioned Eqn 1.

**Superoxide scavenging activity**
The superoxide scavenging activity of methanol extract was determined by the method described by Nishimik et al., with slight modification. About 1.0 ml NBT solution containing 156 µM NBT dissolved in 1.0 ml 100 mM phosphate buffer, pH 7.4, 1.0 ml NADH solution containing 468 µM NADH dissolved in 1.0 ml 100mM phosphate buffer, pH 7.4, and 0.1 ml of various concentration of the methanol extract as well as fraction A (25, 50 µg.ml⁻¹) and standard compound (vitamin E) were mixed and the reaction was started by adding 100 µl of
phenazine methosulfate solution containing 60µM phenazine methosulfate in 100 mM phosphate buffer, pH 7.4. The reaction mixture was incubated at 25°C for 5 min and absorbance at 560 nm was measured against control sample. Percent inhibition was determined by comparing the results of the test and control samples with the above mentioned Eqn 1.

**Antimicrobial activity**

**Bacteria**

A total of 257 bacterial strains belonging to different genera were tested in this study. The test organisms were obtained from Department of Bacteriology, Calcutta School of Tropical Medicine and Institute of Microbial Technology (IMTECH), Chandigarh, India. Three multiresistant Staphylococcus strains (Staphylococcus aureus ML 275, Staphylococcus aureus NCTC 8530 and Staphylococcus epidermidis 865) were kindly provided by Prof. (Mrs.) Sujata Ghosh Dastidar, Department of Pharmacy, Jadavpur University, and Kolkata, India. They were aseptically isolated and identified by the Barrow and Feltham's method and preserved in the freeze-dried state. Gram-positive strains were grown in nutrient broth (NB, Oxoid brand) and Gram-negative bacteria were grown in peptone water (PW, Oxoid brand, bacteriological peptone plus NaCl 0.5%) for 18 h before use.

**Determination of antimicrobial activity**

Sensitivity tests were performed by disc diffusion method. The nutrient agar plates (Oxoid brand), containing an inoculum size of 10^5-10^6 cfu.ml^-1 of bacteria were used. Previously prepared crude methanol extract (Concentration 128-2000 µg.ml^-1) and fraction A (Concentration 128-2000 µg.ml^-1) discs were placed aseptically on sensitivity plates. The discs containing methanol and known antibiotics (Amoxycillin and Gentamicin) served as negative and positive controls. All the plates were then incubated at 37°C±2°C for 18 h. The sensitivity was recorded by measuring the clear zone of inhibition on agar plate around the discs.

The MICs were determined by the standard agar dilution method. All the test compounds were dissolved in methanol. These were then individually added at each final concentrations of 0-2000 µg.ml^-1, to molten agar (Oxoid brand), mixed thoroughly, pH adjusted to 7.2 to 7.4 and poured into sterile Petri dishes. Bacterial cell suspensions were spot inoculated on the plates using a bacterial planter (10 µl). The final number of cfu inoculated onto the agar plates was 10^4 for all strains. The inoculated plates were then incubated at 37°C±2°C for 18 h. The lowest concentration of the plate, which did not show any visible growth after incubation, was considered as MIC. The agar plate containing only methanol and Amoxycillin was served as negative and positive control.

**Statistical analysis**

Data are reported as the mean ± SD of three measurements. Statistical analysis was performed by the student t-test and by ANOVA. IC_{50} values for all the above experiments were determined by linear regression method. A p-value less than 0.05 was considered as indicative of significance.

**Results and Discussion**

**Antioxidant activity**

**Assay of lipid peroxidation**

The results presented in Table-1 showed that the methanol extract of the HNSE inhibited FeSO_4 induced lipid peroxidation in a dose dependent manner. The extract at 1000 µg.ml^-1 exhibited maximum inhibition (69.25 ± 1.21%) of lipid peroxidation, on the other hand fraction A at 50 µg.ml^-1 concentrations showed (72.38 ±1.9%) inhibition, nearly equal to the inhibition produced by vitamin E (Fig 1). The IC_{50} value was found to be 747.5 ±3.16 µg.ml^-1. The inhibition could be caused by the absence of ferryl-perferryl complex or by changing the ratio of Fe^{3+} / Fe^{2+} or by reducing the rate of conversion of ferrous to ferric or by chelating the iron itself or combination thereof.

**DPPH scavenging activity**

DPPH is a stable free radical that can accept an electron or hydrogen radical to become a stable dimagnetic molecule. Due to its odd electron, the
methanolic solution of DPPH shows a strong absorption at 517 nm. DPPH radical reacts with suitable reducing agents and then electrons become paired off and the solution loses colour stoichiometrically with the number of electrons taken up. Such reactivity has been widely used to test the ability of compound/plant extracts to act as free radical scavengers. Reduction of the DPPH radicals can be observed by the decrease in absorbance at 517 nm. The DPPH scavenging capacity of the extract was found to be 72.38 ± 3.92 % at 1000 µg.ml⁻¹. The fraction A at 50 µg.ml⁻¹ on the other hand, exhibited 76.38 ± 5.12 % inhibition compared with 80.46 ± 2.84 % for the standard mannitol.

**Superoxide scavenging activity**

Superoxide radical O₂⁻ is a highly toxic specie, which is generated by numerous biological and photochemical reactions. Both aerobic and anaerobic organisms possess superoxide dismutase enzymes, which catalyse the breakdown of superoxide radical. Reduced phenazine methosulfate assay was used to measure the superoxide dismutase activity of HNSE. The results presented in Table 1 showed that the scavenging capacity of the extract was 60.57 ± 2.34% at 1000 µg.ml⁻¹. The fraction at 25 µg.ml⁻¹ exhibited 68.36 ± 2.73 % inhibition of superoxide radicals. IC₅₀ was found to be 8.9 mg.ml⁻¹. Inhibition was proportional to the amount of the extract added.

**Antimicrobial activity**

The methanol extract of HNSE roots exhibited a significant in vitro antimicrobial activity against 257 Gram-positive and Gram-negative bacteria including multiresistant *Staphylococcus* (MRSC)
Das et al

strains. All the three reference strains of bacteria were found to be sensitive within 1000 µg.ml⁻¹. The preliminary biological screening of the fractions showed that the ethyl acetate part was more active than other fractions (Data not shown). The results of the antimicrobial spectrum of the roots extract presented in Table 2 showed that out of 257 bacteria, the growth of 197 isolates were inhibited at a concentration of 128 – 512 µg.ml⁻¹. 57 isolates were resistant up to 1000µg.ml⁻¹, while the remaining 03 isolates where resistant up to >2000 µg.ml⁻¹, the highest concentration tested. The MICs tests revealed that 63 out of 75 Gram-positive bacteria were sensitive between 128 and 256 µg/ml (zone diameter 10–16 mm); while out of 179 Gram-negative isolates, 120 were sensitive between 256-512 µg.ml⁻¹ (zone diameter 10-14 mm). Hence, it appears that the antimicrobial activity of the methanol extracts was directed both against Gram-positive and Gram-negative bacteria. The ethyl acetate fraction (fraction A) was also tested for antimicrobial activity. The result revealed that all the isolates were sensitive at 128-256 µg.ml⁻¹ (Table 3). It was interesting to note that all the MRSC were susceptible to fraction A at a concentration of 128 µg.ml⁻¹, while they were resistant to the two test antibiotics. Thus, ethyl acetate fraction may become clinically relevant, particularly for antibiotic-resistant strains. However, the activity has to be studied using isolated pure compounds from the fraction to which the more resistant strains were susceptible in order to confirm these findings.
